# CSCI 466: Networks

Wireless Networks, WiFi

Reese Pearsall Fall 2023

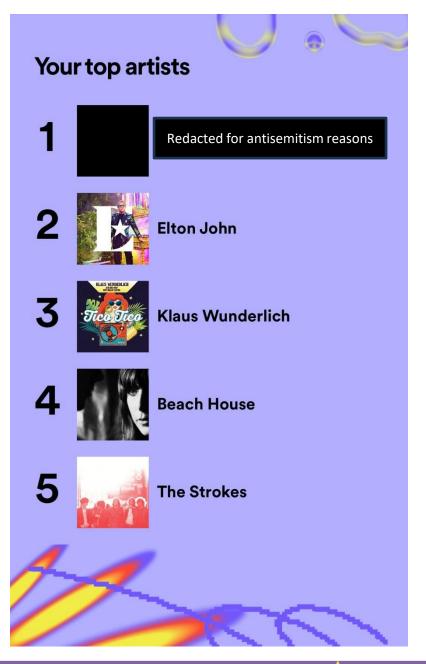

\*All images are stolen from the internet

#### **Announcements**

Quiz on Friday (no class)

- Message Confidentiality (Encryption)
- Message Integrity and Authentication (Hashing)
- Network Attacks (SYN flooding, SYN reset, SYN Hijacking, DNS attacks, BGP attacks)
- Security Protocols (TLS, Ipsec, PGP)
- Operational Security (Firewalls, IDS, IOCs)

Monday (12/4) → Work Day for PA5 (no lecture) Wednesday (12/6) → Review for final exam Friday (12/8) → Final Exam

APPLICATION LAYER 7	Human-computer interaction layer, where applications can access the network services
PRESENTATION LAYER 6	_ Ensures that data is in a usable format and is where data encryption occurs
SESSION LAYER 5	_ Maintains connections and is responsible for controlling ports and sessions
TRANSPORT LAYER 4	Transmits data using transmission protocols including TCP and UDP
NETWORK LAYER 3	— Decides which physical path the data will take
DATA LINK LAYER 2	— Defines the format of data on the network
PHYSICAL LAYER 1	— Transmits raw bit stream over the physical medium

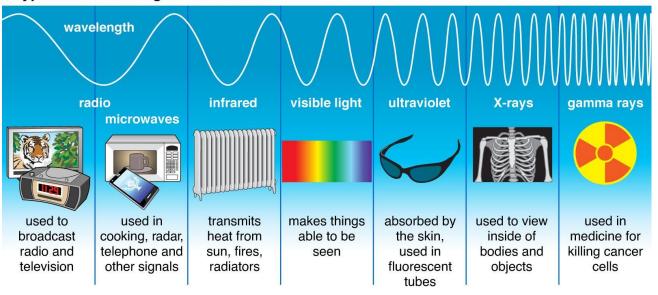

## Wireless and Mobile Networks: context

- more wireless (mobile) phone subscribers than fixed (wired) phone subscribers (10-to-1 in 2019)!
- more mobile-broadband-connected devices than fixed-broadbandconnected devices devices (5-1 in 2019)!
  - 4G/5G cellular networks now embracing Internet protocol stack, including SDN
- two important (but different) challenges
  - wireless: communication over wireless link
  - mobility: handling the mobile user who changes point of attachment to network

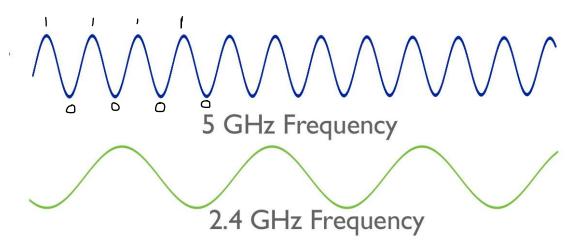

### **Wireless Networks**

Transmission Medium = waves in the air

#### **Types of Electromagnetic Radiation**

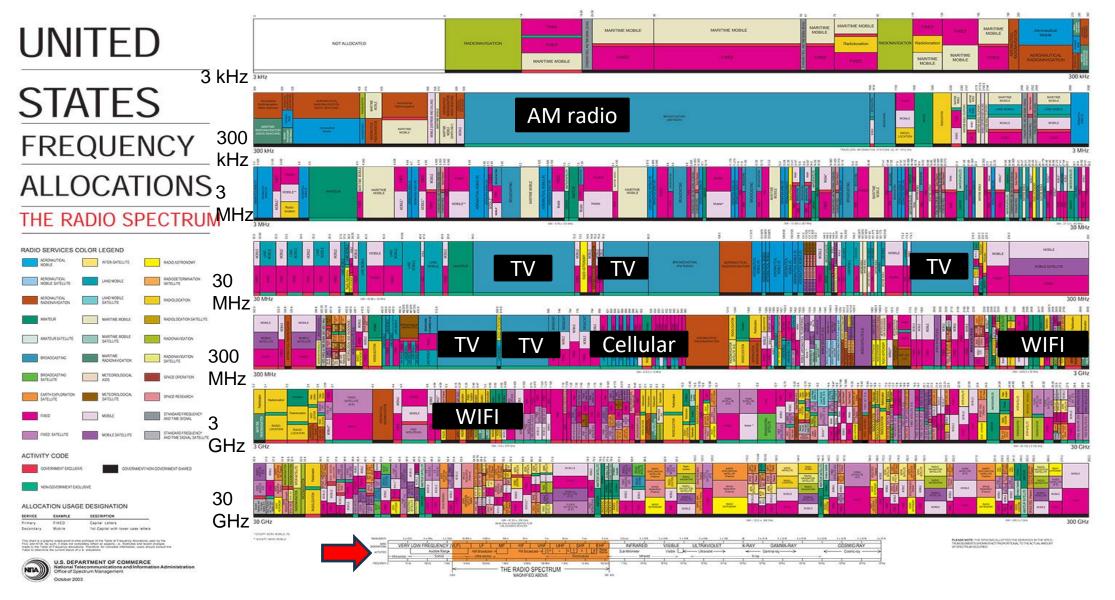

© Encyclopædia Britannica, Inc.

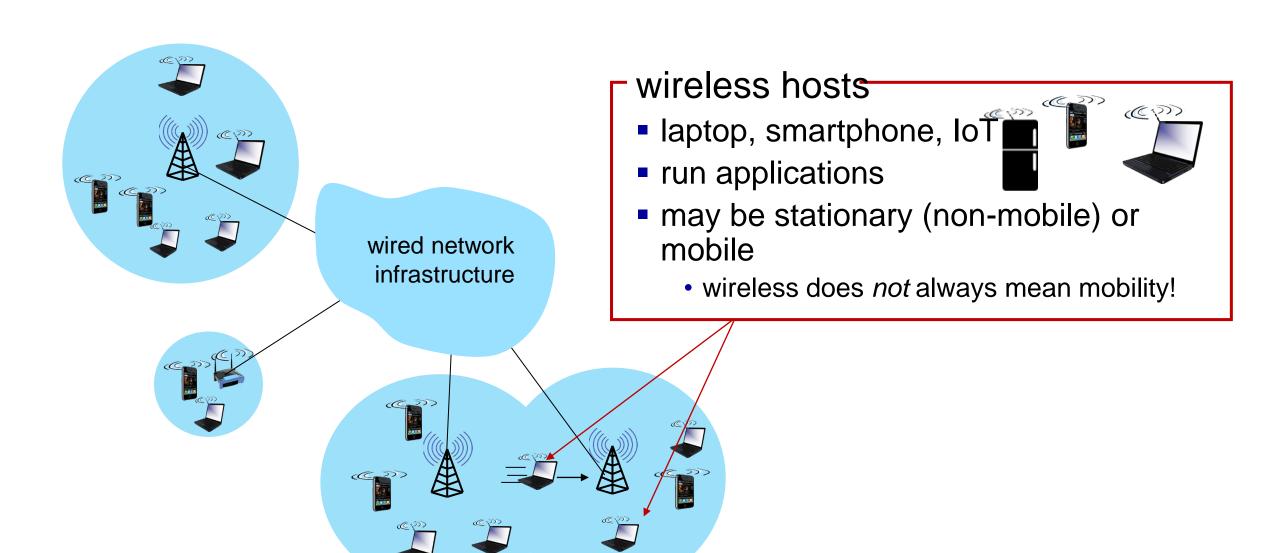

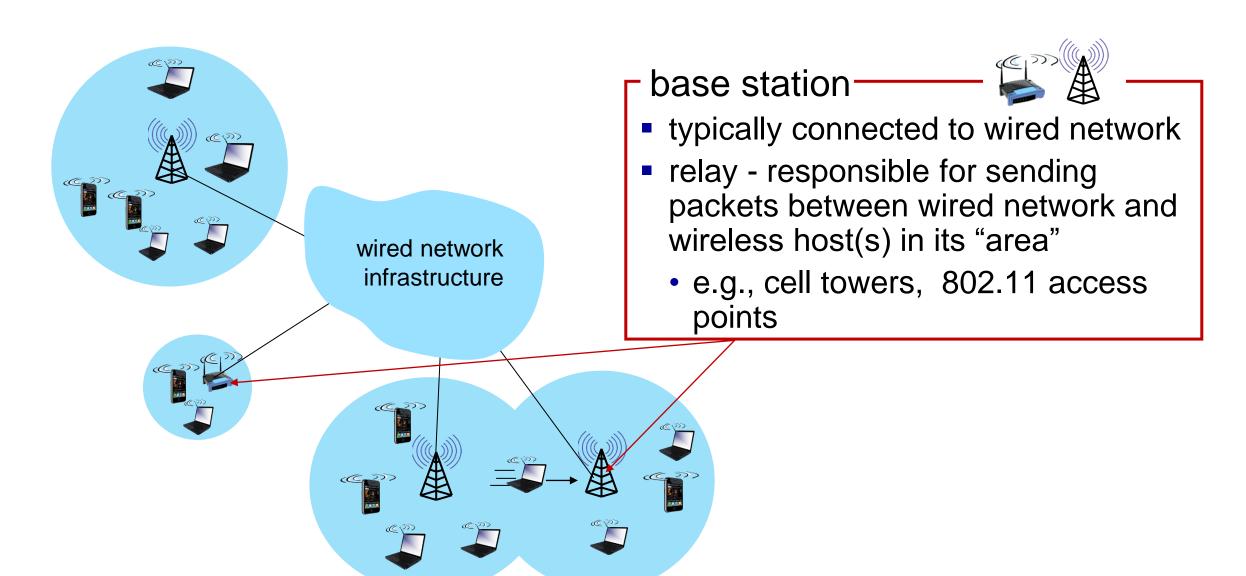

We can transmit waves at different *frequencies* 

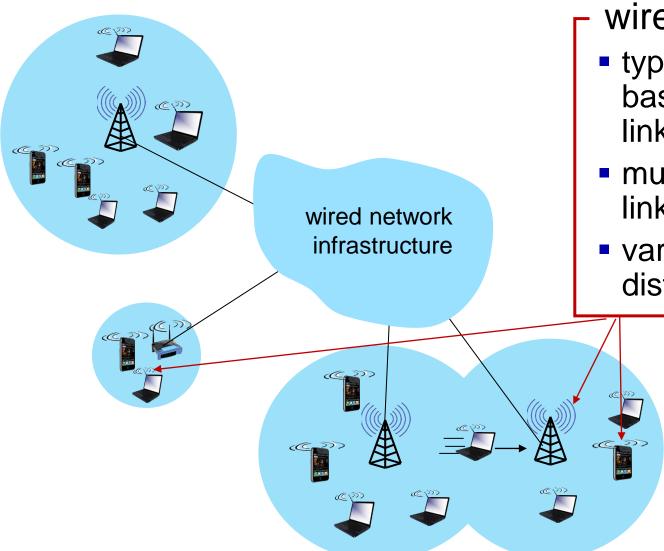

Lower frequency → The farther the wave can travel

The government controls which frequencies should be used for different technologies/services

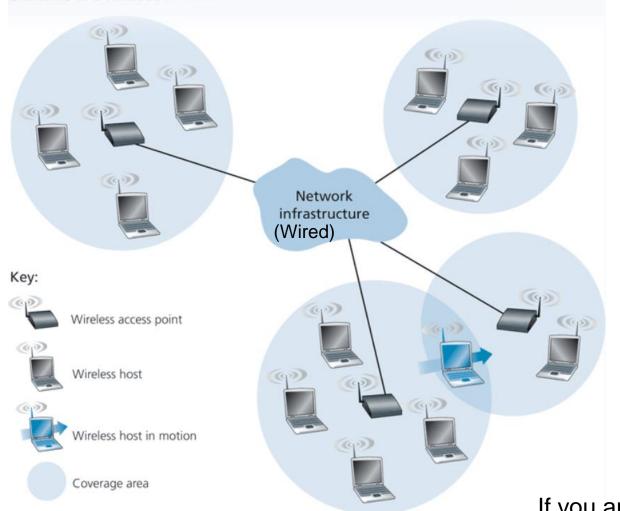

# wireless link——

- typically used to connect mobile(s) to base station, also used as backbone link
- multiple access protocol coordinates link access
- various transmission rates and distances, frequency bands

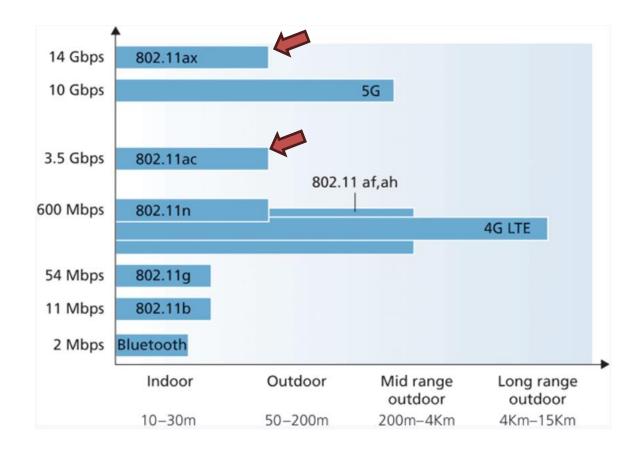

Wireless networks are an *extension* of the standard internet, and usually only occur at the *network edge* 

Wireless hosts connect to a wireless access point that will connect them to the greater internet. Typically linked to a geographic location

**Cell towers** are the access points in cellular networks

If you are not in range of a wireless access point, you will not be able to connect to the internet

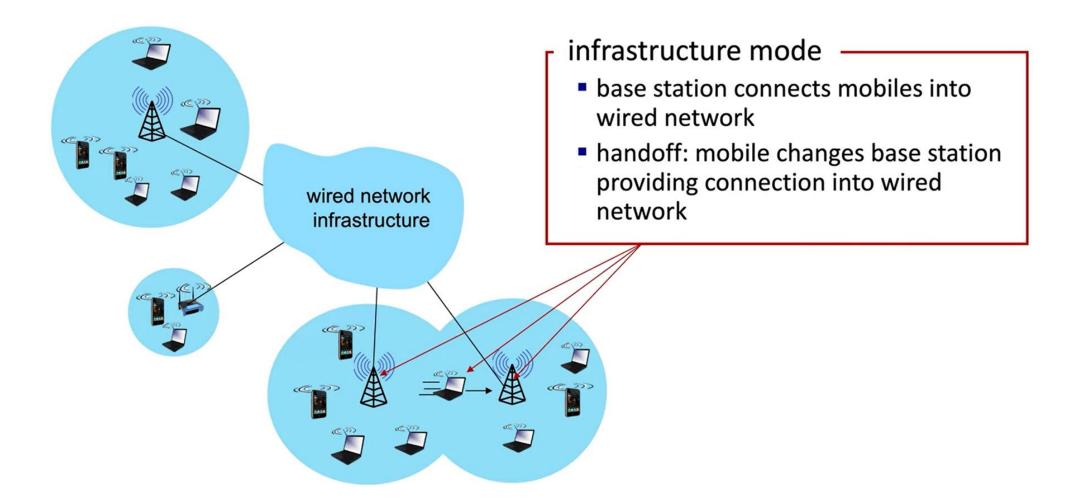

Easer to create high bandwidth links over high frequency carriers, but higher frequencies lose energy more rapidly and it propagates

Generally, lower frequencies are better for long distance communication

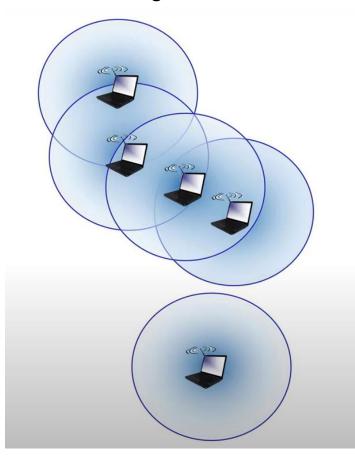

802.11 = WiFi

(These are just Wireless and wireless LAN protocols, there are many more ways!)

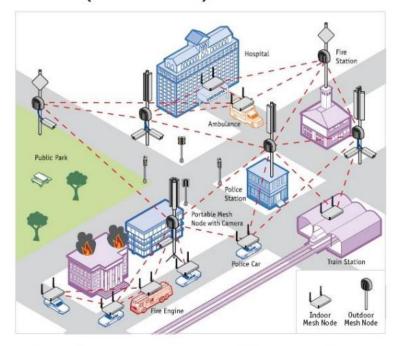

#### Ad hoc mode

- No base stations
- Nodes can only transmit to other nodes within link coverage
- Nodes organize themselves into a network: route amongst themselves

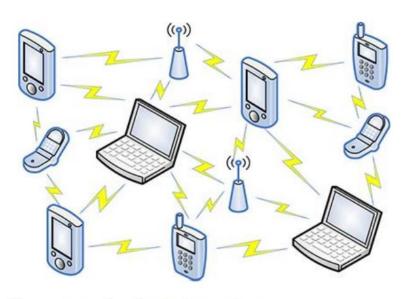

## Mesh (Ad Hoc) Mode

Nodes themselves must provide services such as DNS and DHCP

#### Mobile Ad Hoc Nets (MANETs)

No central administration

This is advantageous where infrastructure may be damaged or not available

## Wireless network taxonomy

	single hop	multiple hops	
infrastructure (e.g., APs)	host connects to base station (WiFi, cellular) which connects to larger Internet	host may have to relay through several wireless nodes to connect to larger Internet: <i>mesh net</i>	
no infrastructure	no base station, no connection to larger Internet (Bluetooth, ad hoc nets)	no base station, no connection to larger Internet. May have to relay to reach other a given wireless node MANET, VANET	

## Wireless link characteristics: fading (attenuation)

Wireless radio signal attenuates (loses power) as it propagates (free space "path loss")

Free space path loss ~ (fd)<sup>2</sup>

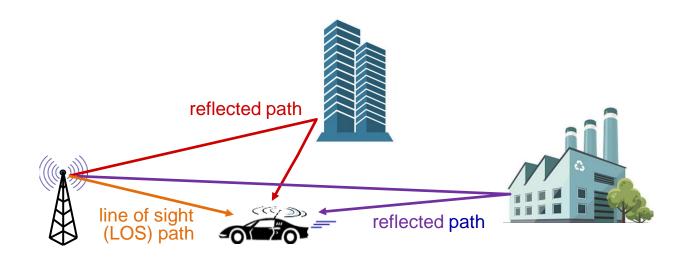

f: frequency
d: distance

higher frequency
or longer distance

| larger free space
path loss

## Wireless link characteristics: multipath

multipath propagation: radio signal reflects off objects ground, built environment, arriving at destination at slightly different times

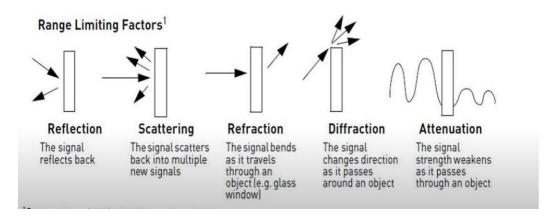

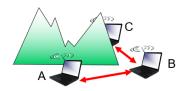

## Wireless link characteristics: multipath

Important differences from wired link...

- Decreased signal strength: radio signal attenuates as it propagates through matter (path loss)
- Interference from other sources: wireless network frequencies (such as 2.4 ghz) shared by many devices will cause interferences
- Multipath propagation: radio signal reflects off objects ground, arriving at destination at slightly different speeds

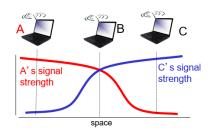

This makes wireless link communication much more challenging, compared to wired links

#### Hidden terminal problem

- B, A hear each other
- B, C hear each other
- A, C can not hear each other means A, C unaware of their interference at B

#### Signal attenuation:

- B,A hear each other
- B. C hear each other
- A, C can not hear each other interfering at B

## Wireless link characteristics: multipath

Wireless links have a threshold value they must operate over

→ If the wireless link does not meet this threshold, then a receiver cannot extract signal

#### **SNR:** signal-to-noise ratio

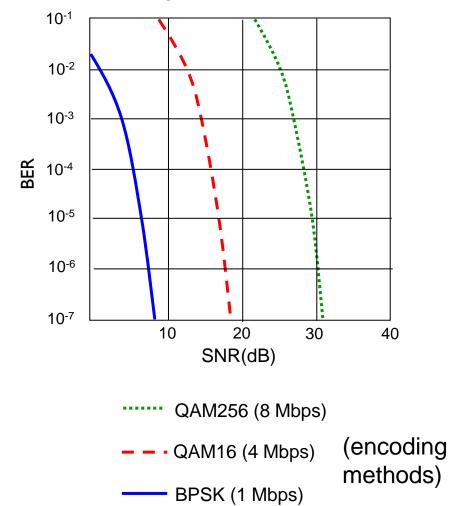

→ Larger SNR – easier to extract signal from noise (more power) (good thing)

#### **BER: Bit Error Rate**

→ Large BER – data is corrupted more frequently

#### **SNR vs BER tradeoff**

- Given physical layer. increase power → increase SNR → decrease BER
- Given SNR: choose physical layer that meets BER requirement, giving highest throughput

### **Shared Medium**

 Because wireless networks are sharing a medium/frequency, we need mechanisms for sharing bandwidth so that collisions don't occur

- In the link layer we have three types
- **1. TDMA** (Time division Multiple Access)
- 2. FDMA (Frequency Division Multiple Access)
- **3. CDMA** (Code Division Multiple Access)

Wired Networks

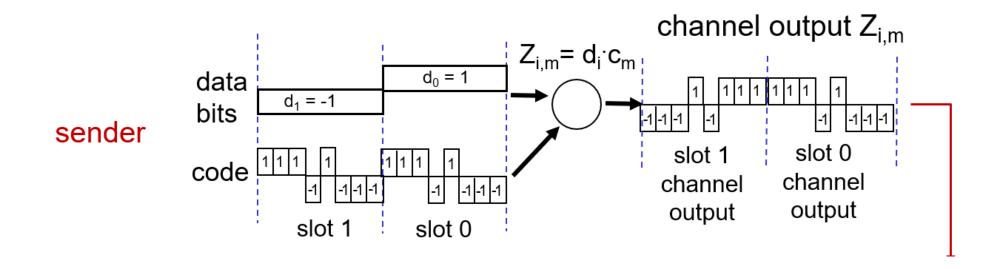

Wireless Networks

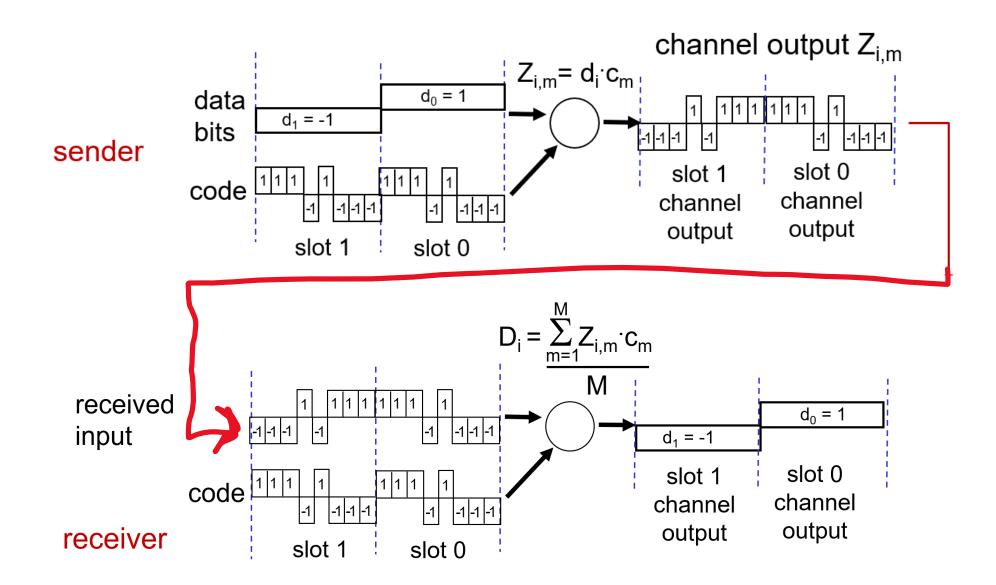

#### **CDMA** (Code Division Multiple Access)

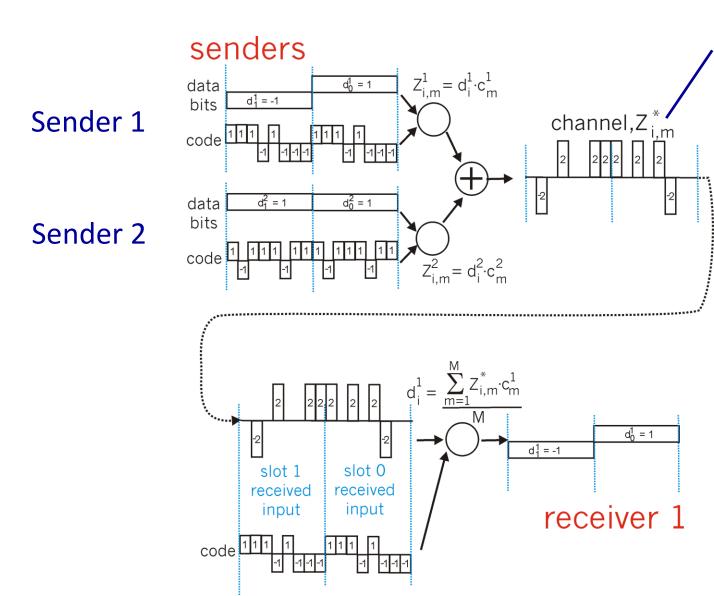

All users transmit on the same frequency, but are assigned a unique code (chipping sequence)

In a CDMA protocol, each bit being sent is encoded by multiplying the bit by a signal (the code)

- Encoding: inner product: (original data) \* (chipping sequence)
- **Decoding**: summed inner-product: (encoded data) \* (chipping sequence)

channel sums together transmissions by sender 1 and 2

using same code as sender 1, receiver recovers sender 1's original data from summed channel data!

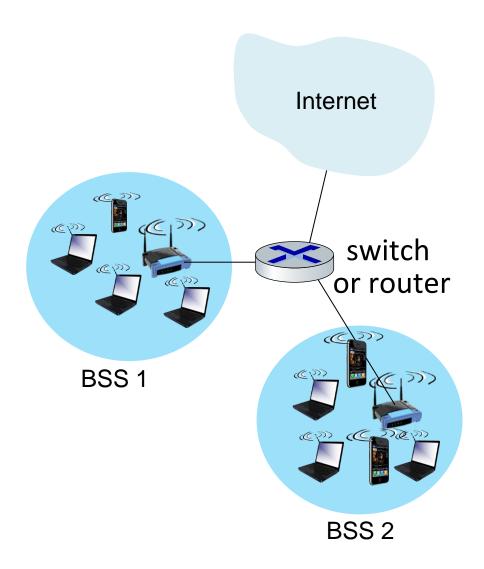

... now that's useful!

## **IEEE 802.11 Wireless LAN**

IEEE 802.11 standard	Year	Max data rate	Range	Frequency
802.11b	1999	11 Mbps	30 m	2.4 Ghz
802.11g	2003	54 Mbps	30m	2.4 Ghz
802.11n (WiFi 4)	2009	600	70m	2.4, 5 Ghz
802.11ac (WiFi 5)	2013	3.47Gpbs	70m	5 Ghz
802.11ax (WiFi 6)	2020 (exp.)	14 Gbps	70m	2.4, 5 Ghz
802.11af	2014	35 – 560 Mbps	1 Km	unused TV bands (54-790 MHz)
802.11ah	2017	347Mbps	1 Km	900 Mhz

all use CSMA/CA for multiple access, and have base-station and adhoc network versions

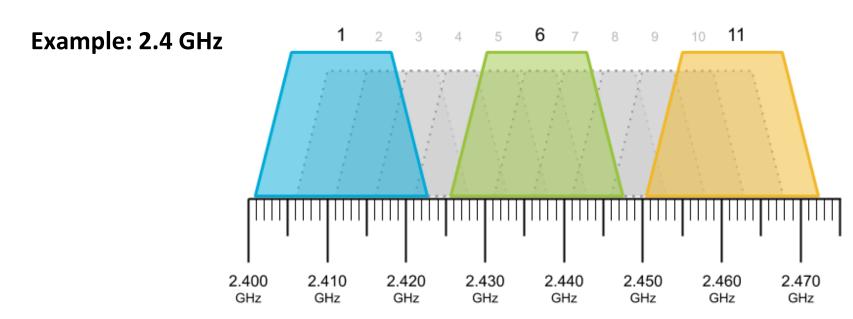

### **IEEE 802.11 Wireless LAN Architecture**

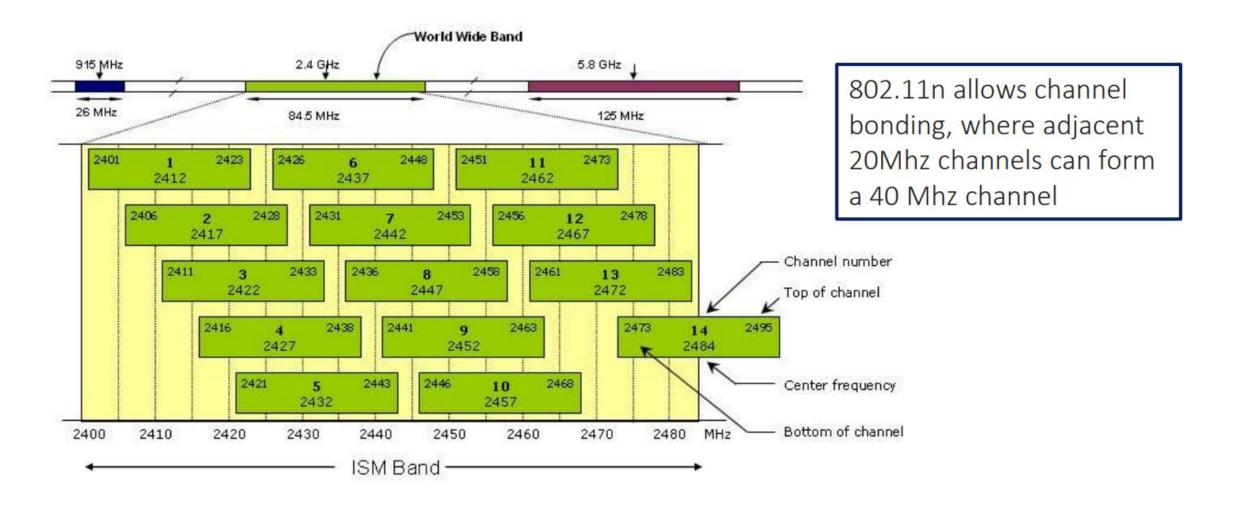

- wireless host communicates with base station
  - base station = access point (AP)
- Basic Service Set (BSS) (aka "cell") in infrastructure mode contains:
  - wireless hosts
  - access point (AP): base station
  - ad hoc mode: hosts only

## **802.11: Channels**

- spectrum divided into channels at different frequencies
  - AP admin chooses frequency for AP
  - interference possible: channel can be same as that chosen by neighboring AP!

## **802.11: Channels**

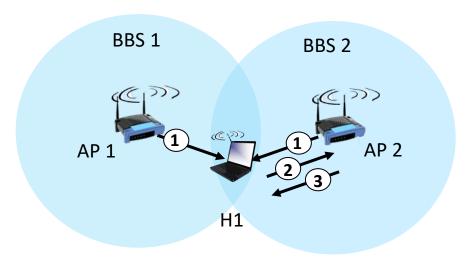

## 802.11: Association

- arriving host: must associate with an AP
  - scans channels, listening for beacon frames containing AP's name (SSID) and MAC address
  - selects AP to associate with
  - then may perform authentication
  - then typically run DHCP to get IP address in AP's subnet

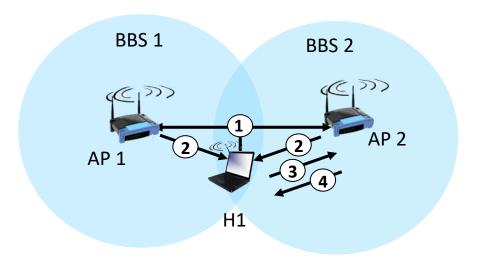

**BSS** 

## 802.11: Association

## passive scanning:

- (1) beacon frames sent from APs
- (2) association Request frame sent: H1 to selected AP
- (3) association Response frame sent from selected AP to H1

## active scanning:

- (1) Probe Request frame broadcast from H1
- (2) Probe Response frames sent from APs
- (3) Association Request frame sent: H1 to selected AP
- (4) Association Response frame sent from selected AP to H1

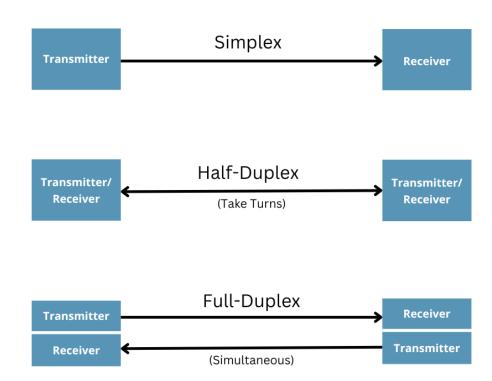

## 802.11: Association

In (wired) ethernet, we had MAC protocols that would listen on a channel, and only transmit if the channel was empty

• → Requires the ability to **listen** and **transmit** at the same time (full-duplex)

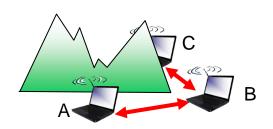

When WiFi begins to transmit a frame, it transmits the frame in its entirety; there is no going back

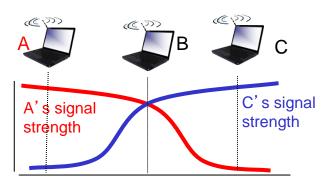

WiFi is not full-duplex, which means it cannot *detect* collisions, so we must *avoid* collisions instead

## **IEEE 802.11:** multiple access

- avoid collisions: 2+ nodes transmitting at same time
- 802.11: CSMA sense before transmitting
  - don't collide with detected ongoing transmission by another node
- 802.11: no collision detection!
  - difficult to sense collisions: high transmitting signal, weak received signal due to fading
  - can't sense all collisions in any case: hidden terminal, fading
  - goal: *avoid collisions:* CSMA/CollisionAvoidance

## IEEE 802.11 MAC Protocol: CSMA/CA

#### 802.11 sender

(time to wait before transmitting)

1 if sense channel idle for **DIFS** then transmit entire frame (no CD)

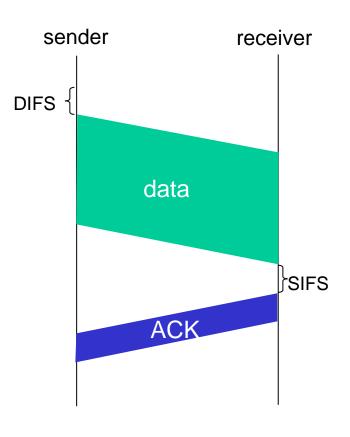

2 if sense channel busy then start random backoff time timer counts down while channel idle transmit when timer expires if no ACK, increase random backoff interval, repeat 2

#### 802.11 receiver

if frame received OK return ACK after **SIFS** (ACK needed due to hidden terminal problem)

# Distributed Inter-frame Space (DIFS)

# **Short Inter-frame Spacing** (SIFS)

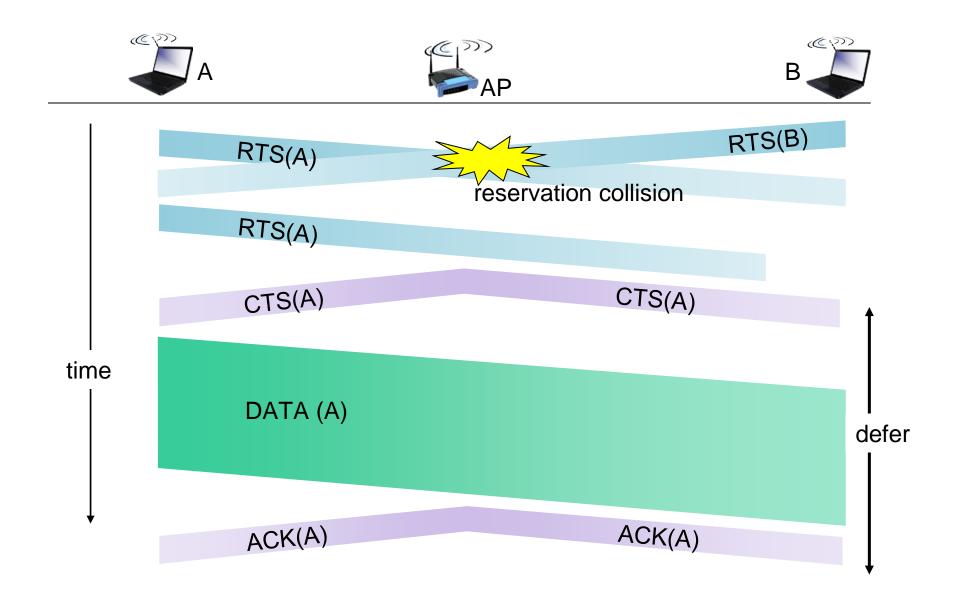

## IEEE 802.11 MAC Protocol: CSMA/CA

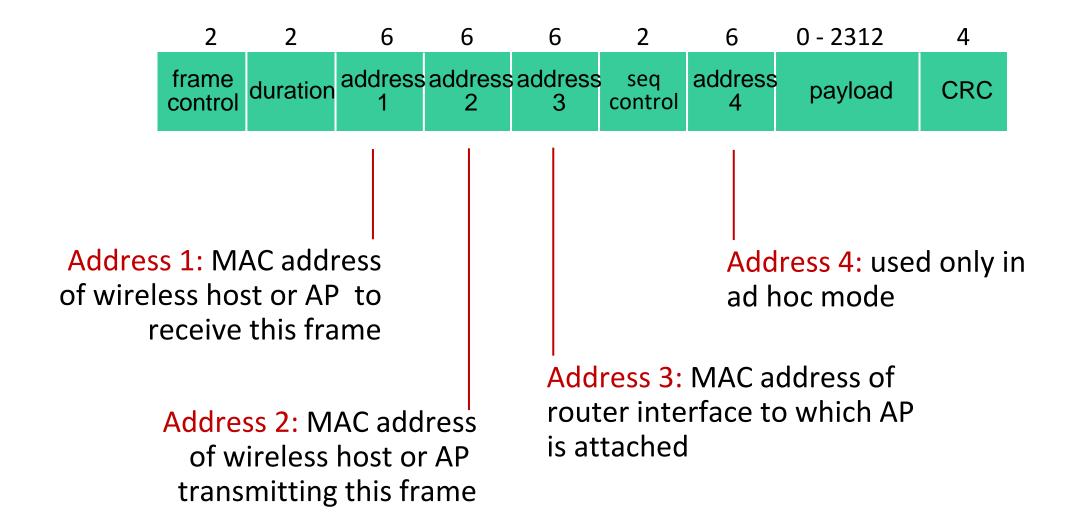

idea: sender "reserves" channel use for data frames using small reservation packets

- sender first transmits small request-to-send (RTS) packet to BS using CSMA
  - RTSs may still collide with each other (but they're short)
- BS broadcasts clear-to-send CTS in response to RTS
- CTS heard by all nodes
  - sender transmits data frame
  - other stations defer transmissions

## IEEE 802.11 MAC Protocol: CSMA/CA

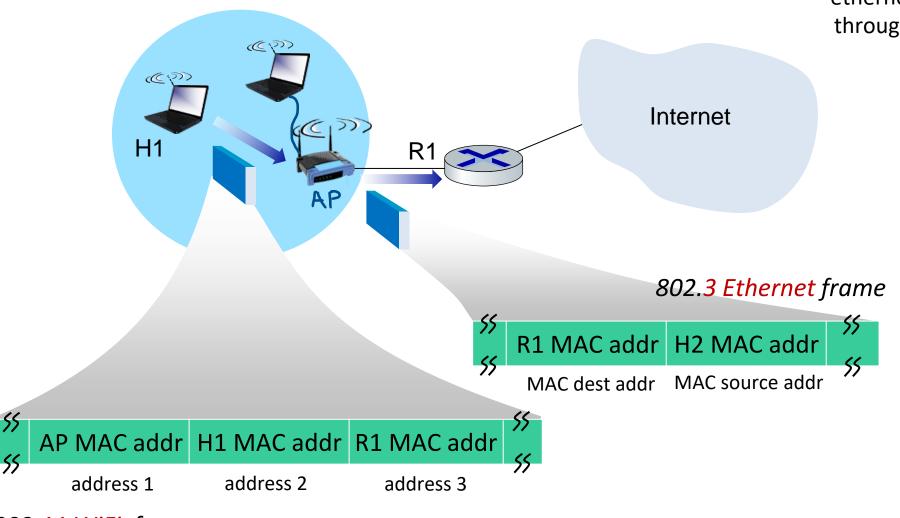

## IEEE 802.11 frame: addressing

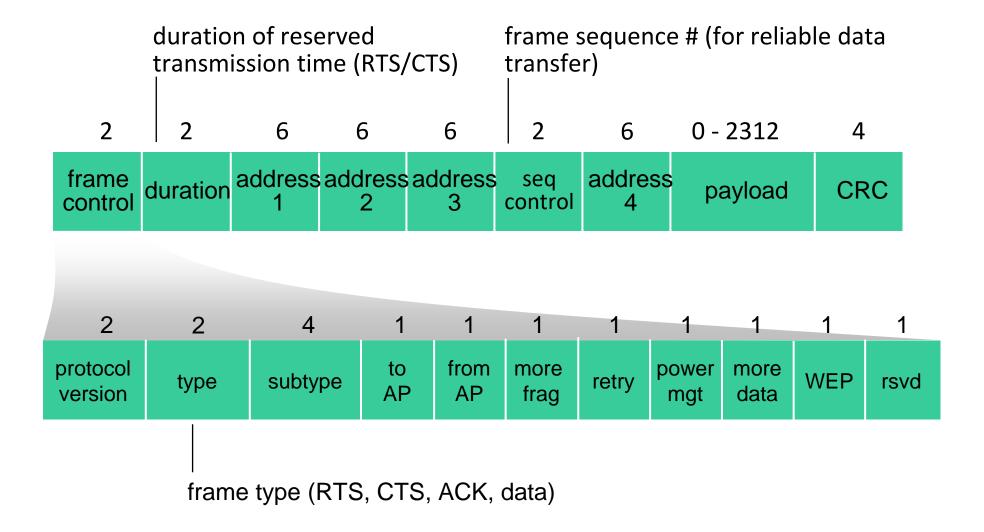

## IEEE 802.11 frame: addressing

Once the AP gets the WiFi frame, it can convert it to a ethernet frame and send it through the main internet

802.11 WiFi frame

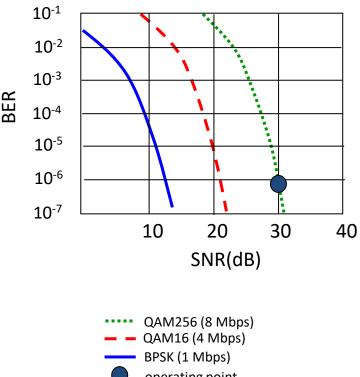

## IEEE 802.11 frame: addressing

## **802.11:** advanced capabilities

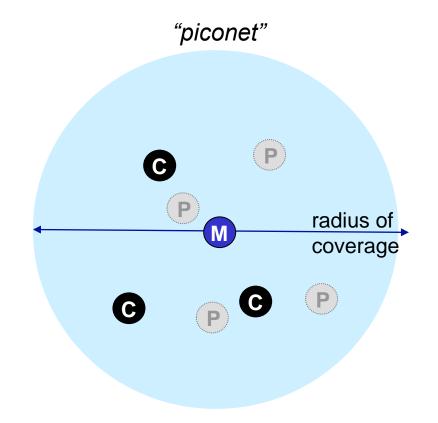

## Rate adaptation

- base station, mobile dynamically change transmission rate (physical layer modulation technique) as mobile moves, SNR varies
  - 1. SNR decreases, BER increase as node moves away from base station
  - 2. When BER becomes too high, switch to lower transmission rate but with lower BER

## Personal area networks: Bluetooth

- less than 10 m diameter
- replacement for cables (mouse, keyboard, headphones)
- ad hoc: no infrastructure
- 2.4-2.5 GHz ISM radio band, up to 3 Mbps
- master controller / client devices:
  - master polls clients, grants requests for client transmissions

- master controller
- c client device
- P parked device (inactive)
