## CSCI 132: Basic Data Structures and Algorithms

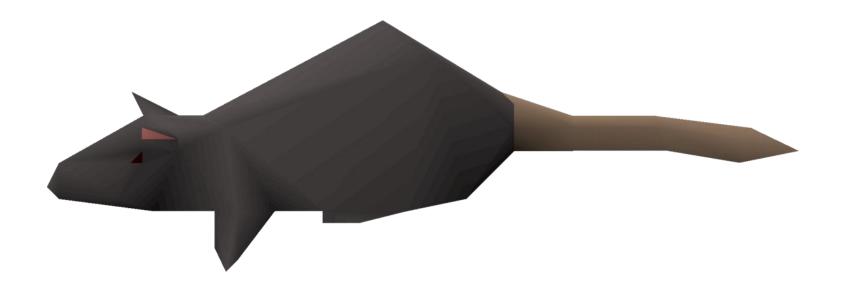

Sorting (Merge Sort)

Reese Pearsall Spring 2025

## Announcements

No class next Friday (University Day)

Would you rather fight 1000 rats all at once, or 1000 rats one after another?

**Merge Sort** is a sorting algorithm that works by <u>dividing</u> an array into smaller subarrays, sorting each subarray, and then <u>merging</u> the subarrays back together to form the final sorted array

Merge sort is a **Divide and Conquer** algorithm, which involves dividing the problem into smaller sub-problems (divide), recursively solving the smaller problems (conquer), and combining the sub problems to get the final solution for the original problem

Merge sort and the next sorting algorithm we will discuss next week are rather complex. I don't expect you to memorize the code, and if you don't fully understand the code, that is fine!

You should, however, be able to describe how merge sort works from a high level, and be able to draw out the steps if given an example array

You should also know the time complexity of the sorting algorithms that we talk about

38 27	43 3	9	82	10	
-------	------	---	----	----	--

Goal: Divide array into two subarrays using recursion:

Base Case:

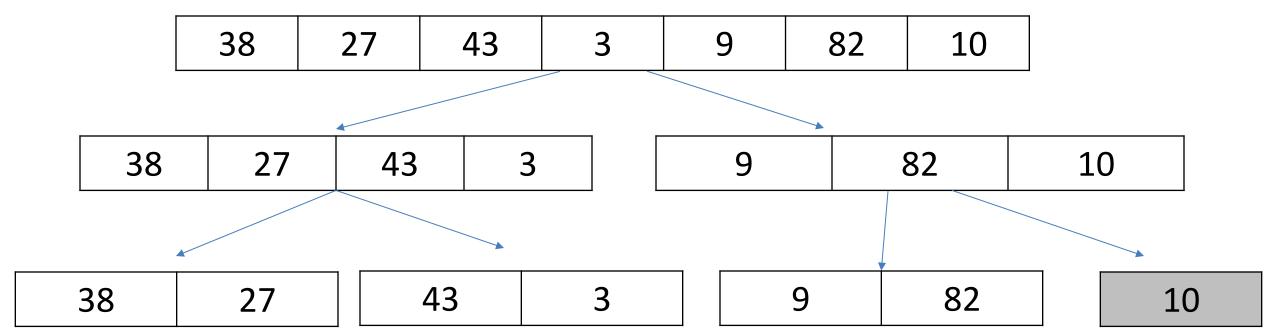

If an array is of size 1, return

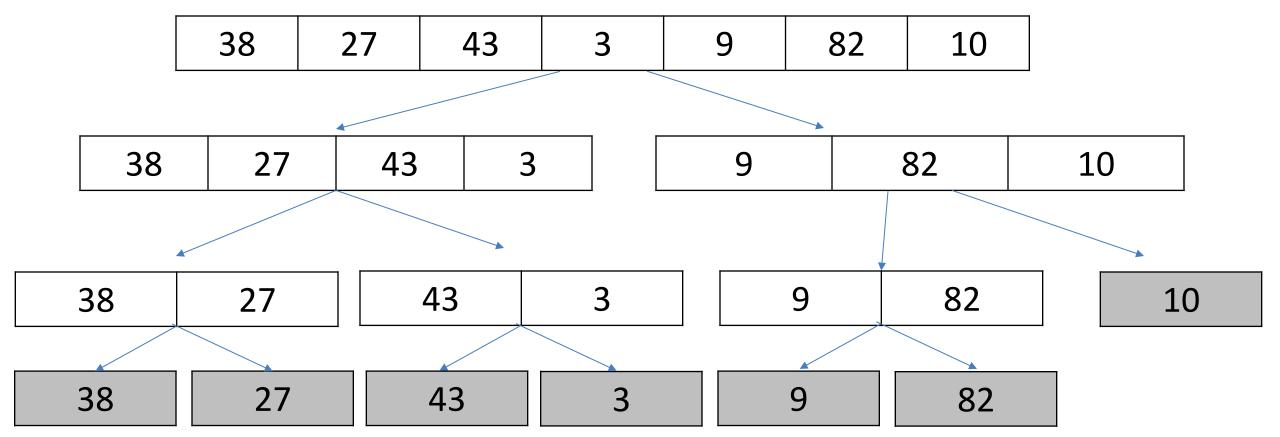

**Recursive Case:** 

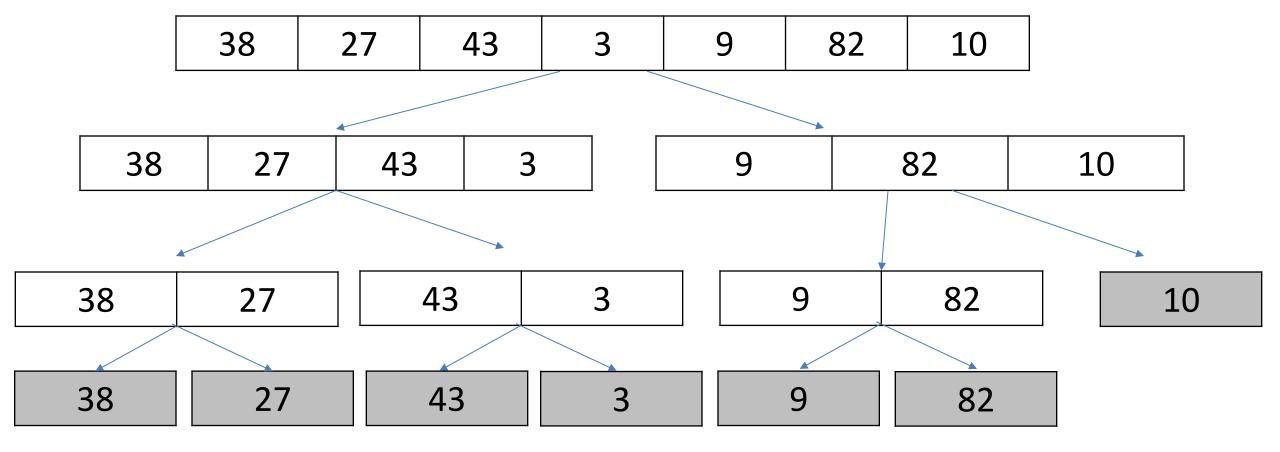

Generate two subarrays leftArray, and rightArray
mergeSort(leftArray), mergeSort(rightArray)

We've hit all our base cases (arrays of size 1), now we will begin to **merge** the subarrays

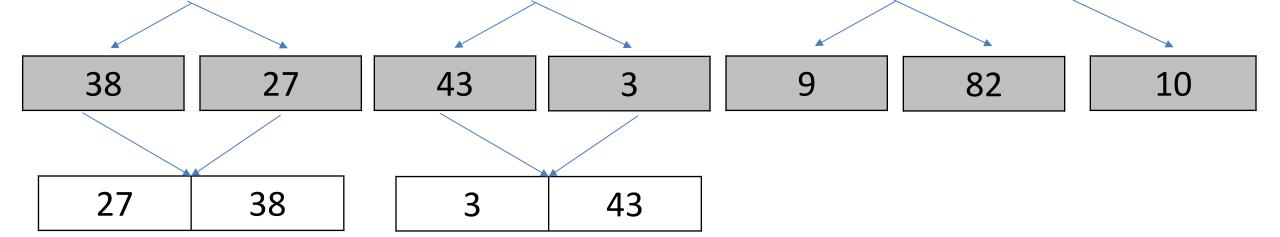

When we merge, our merged array will be sorted

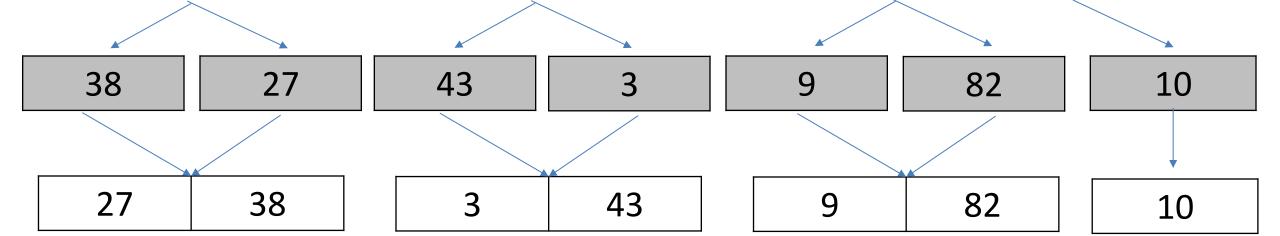

We've hit all our base cases (arrays of size 1), now we will begin to merge the subarrays

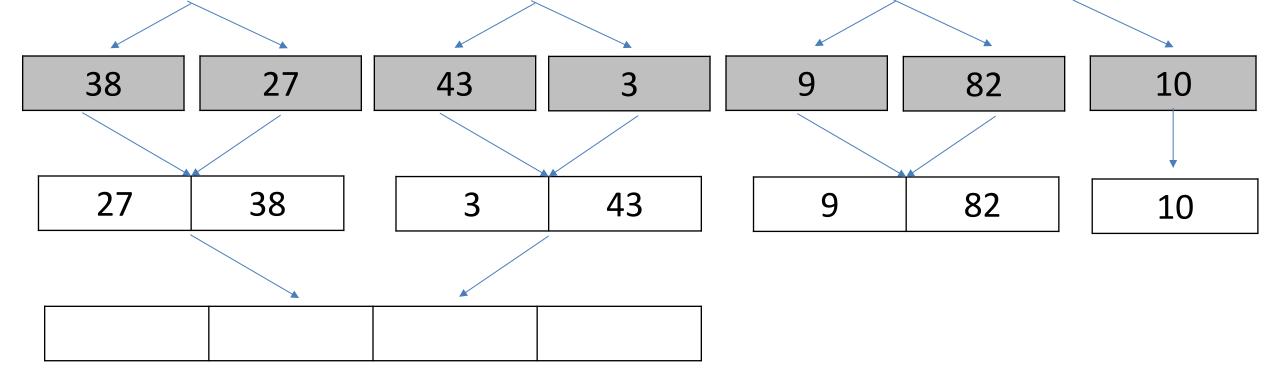

When we merge, our merged array will be sorted

Our original array is now sorted!!

38 27 43 3 9 82 10
--------------------

In our Java code, this will actually be the order of how things are done...

In practice, we will always prioritize solving the "left" tree first

# Running time of merge sort??

## Running time of merge sort??

Running time = number of recursive calls made\* · amount of work done in each call

\*for merge sort, this won't lead us to the correct answer

```
public static int[] merge sort(int[] inputArray) {
  int inputLength = inputArray.length;
  if (inputLength < 2) {</pre>
    return inputArray;
  int midIndex = inputLength / 2;
  int[] leftHalf = new int[midIndex];
  int[] rightHalf = new int[inputLength - midIndex];
  for (int i = 0; i < midIndex; i++) {</pre>
    leftHalf[i] = inputArray[i];
  for (int i = midIndex; i < inputLength; i++) {</pre>
    rightHalf[i - midIndex] = inputArray[i];
 merge_sort(leftHalf);
 merge sort(rightHalf);
  inputArray = merge(inputArray, leftHalf, rightHalf);
  return inputArray;
```

```
public static int[] merge sort(int[] inputArray) {

  return inputArray; O(1)
```

### Running time of merge sort??

Running time = number of recursive calls made\* · amount of work done in each call

Running time =

???

\*

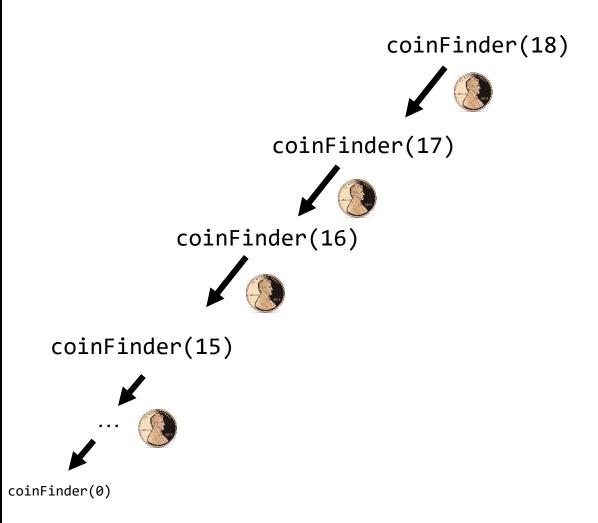

**O(n)** 

\*for merge sort, this won't lead us to the correct answer

### **Merge Sort** mergeSort() mergeSort()

mergeSort()

## Change Making (coinFinder)

Running time = number of recursive calls made\* · amount of work done in each call

Running time =

???

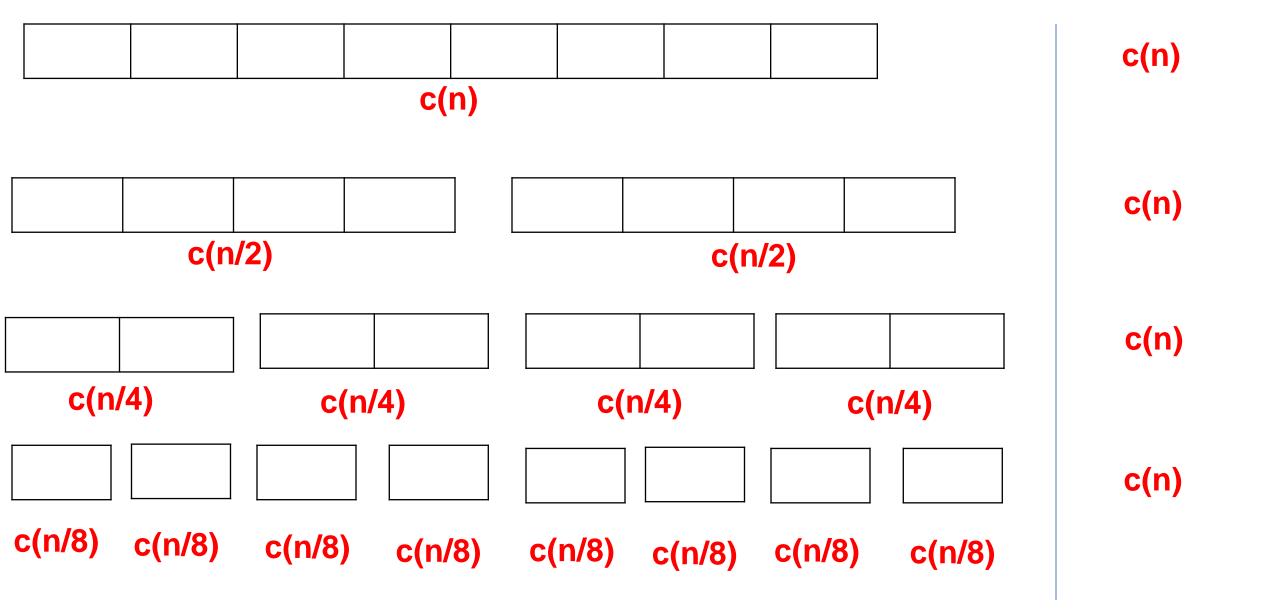

\*

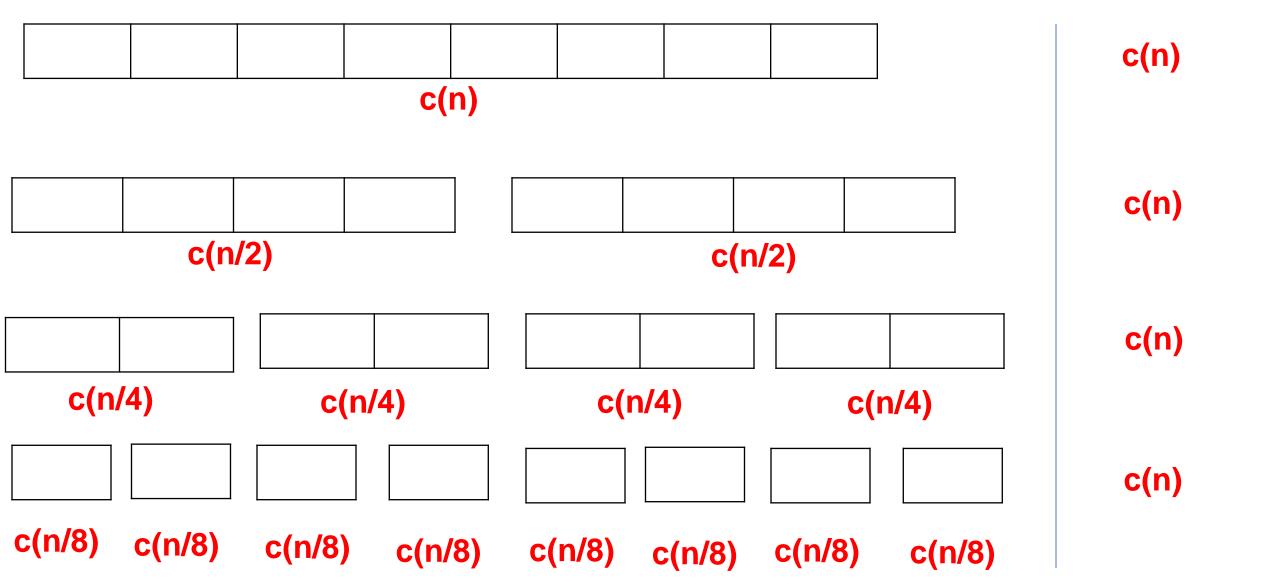

**O(n)** 

When we recursively call our method when dividing, we give a problem that is half the size of the original problem

		c(n)
--	--	------

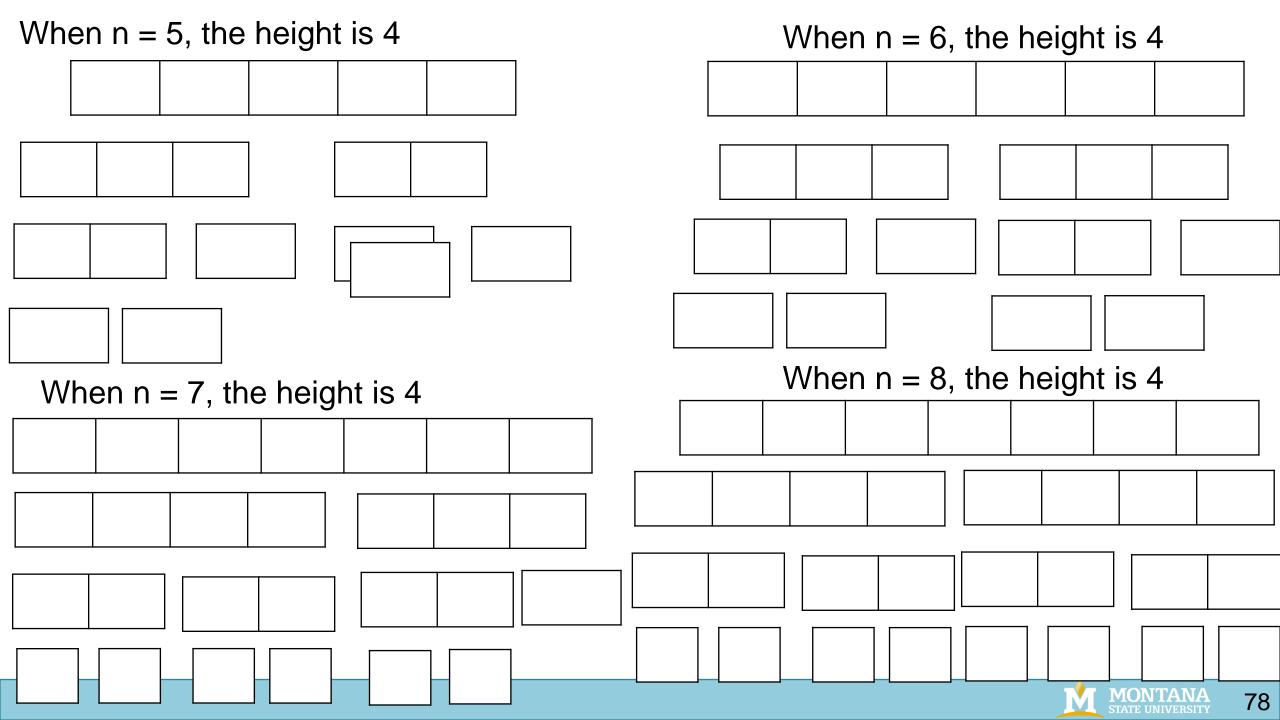

Suppose that the cost of solving a problem of size n can be expressed as c(n)

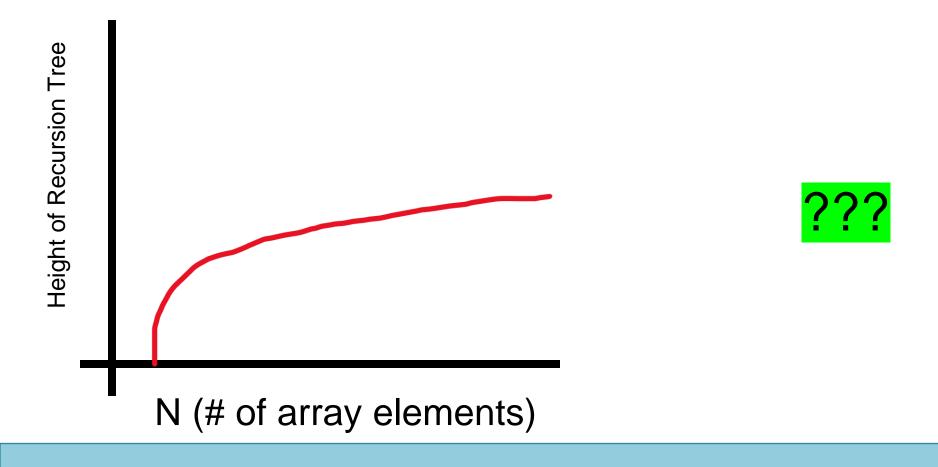

How much do we divide (*in regards to n*)? AKA **what is the height of the recursion tree**?

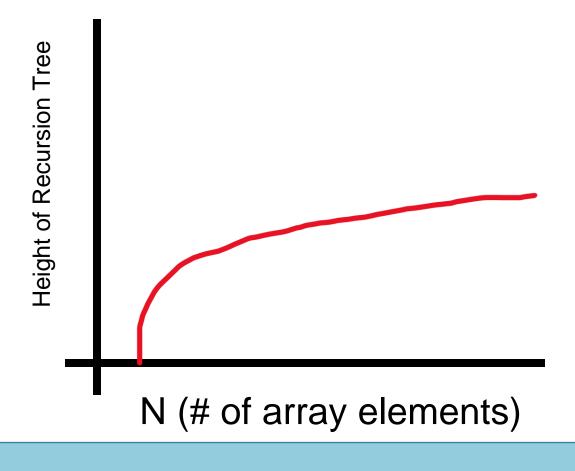

If we were to continue this counting, the graph would look something like this:

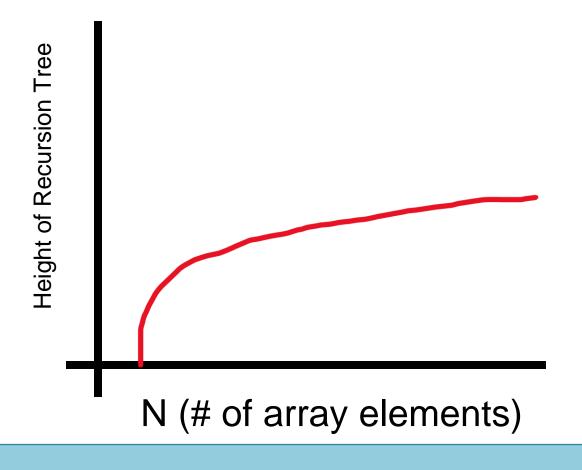

If we were to continue this counting, the graph would look something like this:

log(n)

If we were to continue this counting, the graph would look something like this:

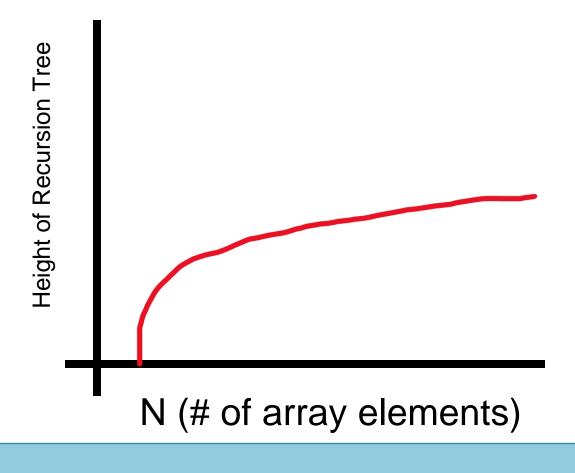

# Logarithmic!!

 $log_2(n)$ 

It will actually be log base 2, because we are dividing our array in half in each recursive call

However, in computer science, all logarithms are to the base 2 unless specified otherwise

If we were to continue this counting, the graph would look something like this:

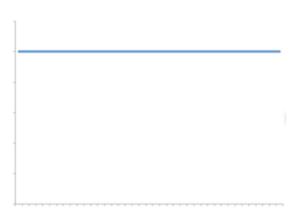

log(n)

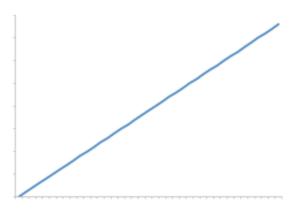

### **Growth Rates**

We have a new member of the family!

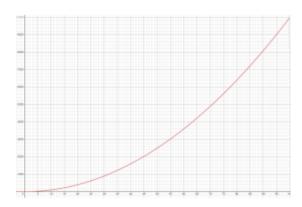

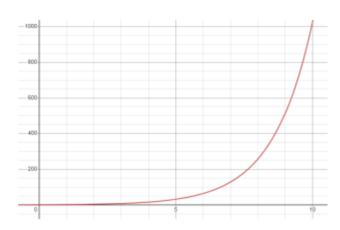

Linear

### Quadratic

# **Exponential**

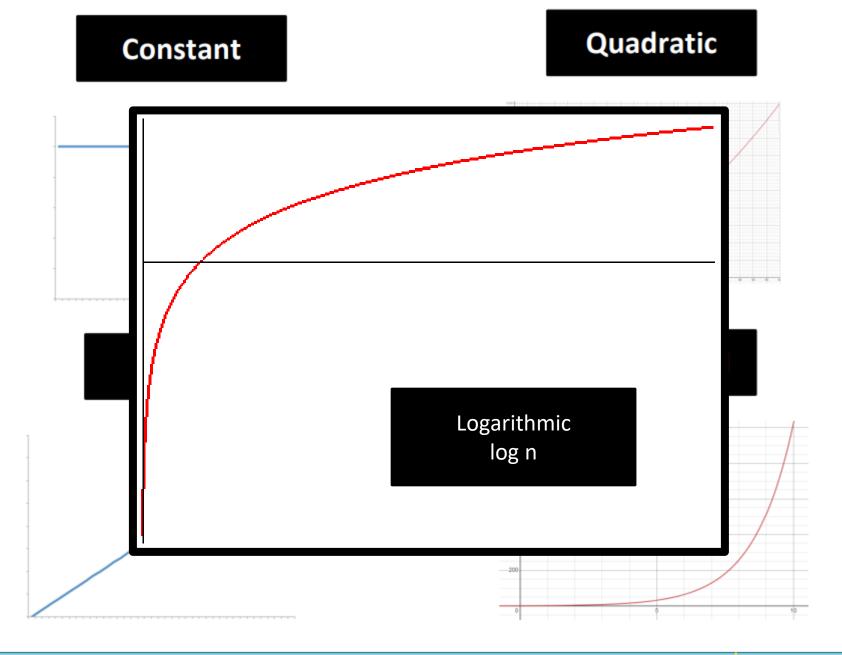

#### **Growth Rates**

We have a new member of the family!

log n is *smaller* than n

algorithms that run in **O(log n)** time are good!

Height of recursive tree

Running time = number of recursive calls made - amount of work done in each call

Running time =

???

O(n)

Height of recursive tree

Running time = number of recursive calls made - amount of work done in each call

Running time =

O(log n)

\*

O(n)

Running time of merge sort = O(n \* log n)

Height of recursive tree

Running time = number of recursive calls made - amount of work done in each call

O(n)

Running time of merge sort = O(n \* log n)

This is **much** faster than O(n^2)
